Joel S. Villasenor Kavli Institute for Astrophysics and Space Science, Massachusetts Institute of Technology, Cambridge, Massachusetts Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA scientific and technical information (STI) program plays a key part in helping NASA maintain this important role. The NASA STI program operates under the auspices of the Agency Chief Information Officer. It collects, organizes, provides for archiving, and disseminates NASA's STI. The NASA STI program provides access to the NTRS Registered and its public interface, the NASA Technical Reports Server, thus providing one of the largest collections of aeronautical and space science STI in the world. Results are published in both non-NASA channels and by NASA in the NASA STI Report Series, which includes the following report types:

- TECHNICAL PUBLICATION. Reports of completed research or a major significant phase of research that present the results of NASA Programs and include extensive data or theoretical analysis. Includes compilations of significant scientific and technical data and information deemed to be of continuing reference value. NASA counterpart of peer-reviewed formal professional papers but has less stringent limitations on manuscript length and extent of graphic presentations.
- TECHNICAL MEMORANDUM. Scientific and technical findings that are preliminary or of specialized interest, e.g., quick release reports, working papers, and bibliographies that contain minimal annotation. Does not contain extensive analysis.
- CONTRACTOR REPORT. Scientific and technical findings by NASA-sponsored contractors and grantees.

• CONFERENCE PUBLICATION.

Collected papers from scientific and technical conferences, symposia, seminars, or other meetings sponsored or co-sponsored by NASA.

- SPECIAL PUBLICATION. Scientific, technical, or historical information from NASA programs, projects, and missions, often concerned with subjects having substantial public interest.
- TECHNICAL TRANSLATION. English-language translations of foreign scientific and technical material pertinent to NASA's mission.

Specialized services also include organizing and publishing research results, distributing specialized research announcements and feeds, providing information desk and personal search support, and enabling data exchange services.

For more information about the NASA STI program, see the following:

- Access the NASA STI program home page at http://www.sti.nasa.gov
- E-mail your question to help@sti.nasa.gov
- Phone the NASA STI Information Desk at 757-864-9658
- Write to: NASA STI Information Desk Mail Stop 148 NASA Langley Research Center Hampton, VA 23681-2199

#### Acknowledgements

These Data Release Notes provide information on the processing and export of data from the Transiting Exoplanet Survey Satellite (TESS). The data products included in this data release are full frame images (FFIs), target pixel files, light curve files, collateral pixel files, cotrending basis vectors (CBVs), and Data Validation (DV) reports, time series, and associated xml files.

These data products were generated by the TESS Science Processing Operations Center (SPOC, Jenkins et al., 2016) at NASA Ames Research Center from data collected by the TESS instrument, which is managed by the TESS Payload Operations Center (POC) at Massachusetts Institute of Technology (MIT). The format and content of these data products are documented in the Science Data Products Description Document (SDPDD)<sup>1</sup>. The SPOC science algorithms are based heavily on those of the Kepler Mission science pipeline, and are described in the Kepler Data Processing Handbook (Jenkins, 2017).<sup>2</sup> The Data Validation algorithms are documented in Twicken et al. (2018) and Li et al. (2019). The TESS Instrument Handbook (Vanderspek et al., 2018) contains more information about the TESS instrument design, detector layout, data properties, and mission operations.

The TESS Mission is funded by NASA's Science Mission Directorate.

# 1 Observations

TESS Sector 22 observations include physical orbits 51 and 52 of the spacecraft around the Earth. Data collection was paused for 1.07 days between the orbits to download data. In total, there are 26.13 days of science data collected in Sector 22.

	UTC	$\mathrm{TJD}^{a}$	Cadence $\#$		
Orbit 51 start	2020-02-19 19:11:21	1899.30103	483729		
Orbit 51 end	2020-03-04 00:01:21	1912.50241	493234		
Orbit 52 start	2020-03-05 01:35:21	1913.56769	494001		
Orbit 52 end	2020-03-17 23:47:20	1926.49269	503307		
<sup><i>a</i></sup> TJD = TESS JD = JD - 2,457,000.0					

Table 1: Sector 22 Observation times

The spacecraft was pointing at RA (J2000): 197.1008°; Dec (J2000): 53.7434°; Roll: -40.3008°. Two-minute cadence data were collected for 20,000 targets, and full frame images were collected every 30 minutes. See the TESS project Sector 22 observation page<sup>3</sup> for the coordinates of the spacecraft pointing and center field-of-view of each camera, as well as the detailed target list. Fields-of-view for each camera and the Guest Investigator two-minute target list can be found at the TESS Guest Investigator Office observations status page<sup>4</sup>.

## 1.1 Notes on Individual Targets

One bright star (Tmag  $\leq 1.8$ ) with a large pixel stamp was not processed in the photometric pipeline. A target pixel file with raw data is provided, but no light curve was produced. The affected TIC ID is 229540730.

Thirteen target stars (900080355, 87480403, 471011933, 471011825, 471011802, 471011722, 310362805, 289622291, 17668162, 159190005, 14725877, 144294174, and 138757095) are blended with comparably bright stars—the contaminating flux for these objects is very large, and the resulting photometry for such targets is expected to be unreliable.

## 1.2 Spacecraft Pointing and Momentum dumps

Camera 1 and Camera 4 were both used for guiding in orbit 51; Camera 4 alone was used for guiding in orbit 52. The reaction wheel speeds were reset with momentum dumps every 6.625 days (orbit 51) or 6.75 days (orbit 52). Figure 1 summarizes the pointing performance over the course of the sector based on Fine Pointing telemetry.

## 1.3 Scattered Light

Figure 2 shows the median value of the background estimate for all targets on a given CCD as a function of time. Figure 3 shows the angle between each camera's boresight and the

<sup>&</sup>lt;sup>3</sup>https://tess.mit.edu/observations/sector-22

<sup>&</sup>lt;sup>4</sup>https://heasarc.gsfc.nasa.gov/docs/tess/status.html

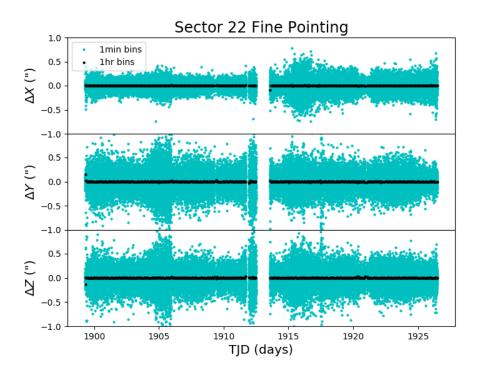

Figure 1: Guiding corrections based on spacecraft fine pointing telemetry. The delta-quaternions from each camera have been converted to spacecraft frame, binned to 1 minute and 1 hour, and averaged across cameras. Long-term trends (such as those caused by differential velocity aberration) have also been removed. The  $\Delta X/\Delta Y$  directions represent offsets along the the detectors' rows/columns, while the  $\Delta Z$  direction represents spacecraft roll.

Earth or Moon—this figure can be used to identify periods affected by scattered light and the relative contributions of the Earth and Moon to the image backgrounds.

In Sector 22, the Earth is a significant source of scattered light at the start of both orbits. The Moon also passes through the field of view of Camera 1 at the start of orbit 52, saturating the detectors.

# 2 Data Anomaly Flags

See the SDPDD (§9) for a list of data quality flags and the associated binary values used for TESS data, and the TESS Instrument Handbook for a more detailed description of each flag.

The following flags were not used in Sector 22: bits 1, 2, 7, 9, and 11 (Attitude Tweak, Safe Mode, Cosmic Ray in Aperture, Discontinuity, Cosmic Ray in Collateral Pixel).

Cadences marked with bits 3, 4, 6, and 12 (Coarse Point, Earth Point, Reaction Wheel Desaturation Event, and Straylight) were marked based on spacecraft telemetry.

Cadences marked with bit 5 and 10 (Argabrightening Events and Impulsive Outlier) were identified by the SPOC pipeline. Bit 5 marks a sudden change in the background measurements. In practice, bit 5 flags are caused by rapidly changing glints and unstable

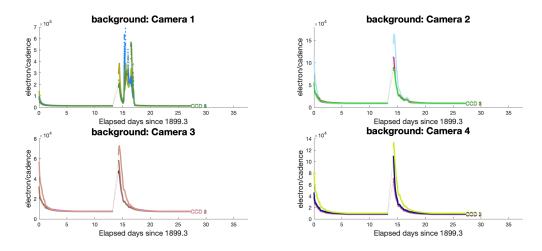

Figure 2: Median background flux across all targets on a given CCD in each camera. The changes are caused by variations in the orientation and distance of the Earth and Moon.

pointing at times near momentum dumps. Bit 10 marks an outlier identified by PDC and omitted from the cotrending procedure.

Cadences marked with bit 8 (Manual Exclude) are ignored by PDC, TPS, and DV for cotrending and transit searches. In Sector 22, these cadences were identified using spacecraft telemetry from the fine pointing system. All cadences with pointing excursions >7 arcseconds ( $\sim 0.3$  pixel) were flagged for manual exclude. See Figure 4 for an assessment of the performance of the cotrending based on the final set of manual excludes.

In Sector 22, the predicted stray light flag (bit 12, value 2048) is disabled for the 2minute data products. Instead, the scattered light exclude flag (bit 13, value 4096) identifies cadences at which individual targets are affected by scattered light. The predicted stray light flag (bit 12) continues to be marked in the FFIs, and flags times when the Earth/Moon are near the camera FOVs and may interfere with guiding or saturate the detectors. We strongly recommend that users inspect the FFI data before removing images marked with bit 12, because this bit is set based on predictions from mission planning and is known to be conservative with respect to the quality of data usable for analysis.

If the Earth/Moon interference is strong enough to saturate the detector, all targets on a CCD slice will be affected and the data are unusable. Cadences with bad calibrations due to saturation are now explicitly marked with bit 15 (value 16384, "Bad Calibration Exclude"). For some cadences, the majority of targets on a CCD may be flagged for scattered light and not enough valid data remains to derive cotrending basis vectors in PDC. No systematic error correction can be applied at these times. This situation is identified by bit 16 (value 32768, "Insufficient Targets for Error Correction Exclude").

FFIs were only marked with bits 3, 6 and 12 (Course Point, Reaction Wheel Desaturation Events and Straylight). Only one FFI is affected by each momentum dump. There are no WCS coordinates for FFIs that coincide with momentum dumps.

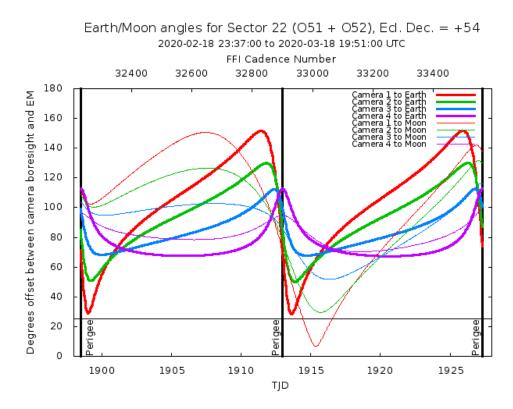

Figure 3: Angle between the four camera boresights and the Earth/Moon as a function of time. When the Earth is within  $\sim 25^{\circ}$  of a camera's boresight, transiting planet searches may be compromised by high levels of scattered light. At larger angles, up to  $\sim 35^{\circ}$ , scattered light patterns and complicated structures may be visible. At yet larger angles, low level patchy features may be visible. Scattered light from the Moon is generally only noticeable below  $\sim 35^{\circ}$ . This figure can be used to identify periods affected by scattered light and the relative contributions of the Earth and Moon to the background. However, the background intensity and locations of scattered light features depend on additional factors, such as the Earth/Moon azimuth and distance from the spacecraft.

# **3** Anomalous Effects

#### 3.1 Smear Correction Issues

The following columns were impacted by bright stars in the science frame, and/or upper buffer rows, and/or lower science frame rows, which bleed into the upper serial register resulting in an overestimated smear correction.

- Camera 1, CCD 1, Column 1971, Star HD 104075
- Camera 1, CCD 3, Column 1222, Star 67 Leo
- Camera 2, CCD 1, Column 621, Star HD 120231
- Camera 2, CCD 2, Column 667, Star HD 105140
- Camera 3, CCD 1, Column 629, Star HD 115612

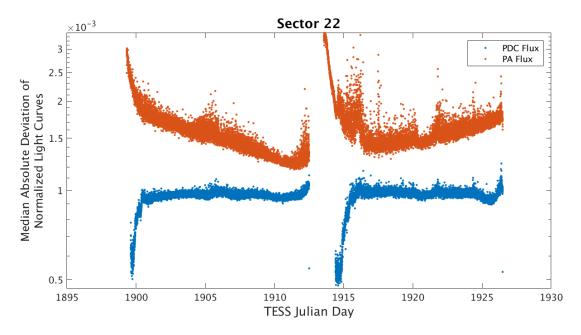

Figure 4: Median absolute deviation (MAD) for the 2-minute cadence data from Sector 22, showing the performance of the cotrending after identifying Manual Exclude data quality flags. The MAD is calculated in each cadence across stars with flux variations less than 1% for both the PA (red) and PDC (blue) light curves, where each light curve is normalized by its median flux value. The scatter in the PA light curves is much higher than that for the PDC light curves, and the outliers in the PA light curves are largely absent from the PDC light curves due to the use of the anomaly flags.

- Camera 3, CCD 1, Column 1506, Star i Draconis
- Camera 3, CCD 3, Column 700, Star HD 131331
- Camera 4, CCD 1, Column 1047, Star Chi Draconis

#### 3.2 Watchdog Resets

A watchdog timer is tripped when the instrument computer unexpectedly hangs, most likely due to space radiation induced errors in the computer processor or memory, resulting in a quick reboot of the computer. This results in a short ( $\approx 4$  minute) gap in data collection and a brief, small pointing excursion.

There were three watchdog timer resets in Sector 22: on 2/29/20, 3/3/20, and 3/12/20. Besides introducing short gaps in the 2m cadence data, these resets resulted in the loss a total of four FFI cadences. Two 2-minute cadences are missing from TJD 1909.46004 to 1909.4642 (2/29/20), from TJD 1911.9267 to 1911.9309 (3/3/20), and from 1921.0560 to 1921.0602 (3/12/20).

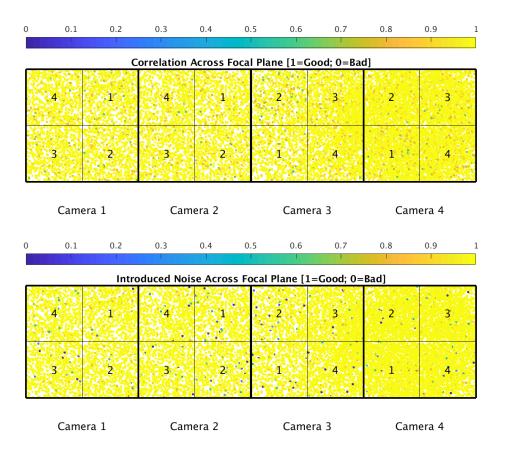

Figure 5: PDC residual correlation goodness metric (top panel) and PDC introduced noise goodness metric (bottom panel). The metric values are shown on a focal plane map indicating the camera and CCD location of each target. The correlation goodness metric is calibrated such that a value greater than 0.8 means there is less than 10% mean absolute correlation between the target under study and all other targets on the CCD. The introduced noise metric is calibrated such that a value greater than 0.8 means the power in broad-band introduced noise is below the level of uncertainties in the flux values.

## **3.3** Fireflies and Fireworks

Table 2 lists all firefly and fireworks events for Sector 22. These phenomena are small, spatially extended, comet-like features in the images—created by sunlit particles in the camera FOV—that may appear one or two at a time (fireflies) or in large groups (fireworks). See the TESS Instrument Handbook for a more complete description.

## **3.4** Corrections to Data Product Timestamps

In Sector 22, an issue was discovered with the assigned timestamps of previously released data products. The reported times are too large by 2 seconds. The issue was caused by an off-by-one error in ground system software that identifies the timestamps of individual two second exposures.

This issue has been fixed for Sector 22 data products, which have updated and accurate

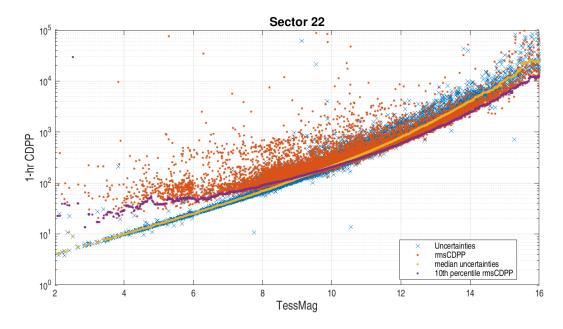

Figure 6: 1-hour CDPP. The red points are the RMS CDPP measurements for the 19999 light curves from Sector 22 plotted as a function of TESS magnitude. The blue x's are the uncertainties, scaled to 1-hour timescale. The purple curve is a moving 10th percentile of the RMS CDPP measurements, and the gold curve is a moving median of the 1-hr uncertainties.

Table 2: Sector Fireflies and Fireworks

FFI Sta	rt FFI I	End Camer	as Description
202006503	2921 20200650	035921 3	Fireflies
202007620	2920 20200762	212920 1,2	Fireflies
202007714	5920 20200771	152920 2	Firefly

timestamps. Timestamps from previous sectors can be corrected by subtracting 2 seconds. Future data releases will include reprocessed data with corrected timestamps.

Two other small adjustments were also made to the timestamps. The start times of integrations for every 2 minute and 30 minute cadence have been shifted forward by 31 milliseconds, and the end times have been shifted forward by 11 milliseconds. These offsets correct for effects in the focal plane electronics that were not accounted for in previous data releases.

Until reprocessed data products are available, the timestamps of FFIs from previous data releases can be corrected by adding these values to the appropriate start and stop times in the image headers. Two-minute data products report the TJD at midexposure, and so should be corrected by adding 21 milliseconds to the timestamps. Note that the correction only applies to the timestamps themselves; the reported exposure times in data product headers and flux values (electrons per second) are correct, as they already account for the 20 millisecond relative offset between start and stop times discussed here.

# 4 Pipeline Performance and Results

### 4.1 Light Curves and Photometric Precision

Figure 5 gives the PDC goodness metrics for residual correlation and introduced noise on a scale between 0 (bad) and 1 (good). The performance of PDC is very good and generally uniform over most of the field of view. Figure 6 shows the achieved Combined Differential Photometric Precision (CDPP) at 1-hour timescales for all targets.

### 4.2 Transit Search and Data Validation

In Sector 22, the light curves of 19999 targets were subjected to the transit search in TPS. Of these, Threshold Crossing Events (TCEs) at the 7.1  $\sigma$  level were generated for 561 targets.

We employed an iterative method when conducting the Sector 22 transit search. The top panel of Figure 7 shows the number of TCEs at a given cadence that exhibit a transit signal from an initial run of TPS. The  $3\sigma$  peaks were used to define deemphasis weights for a second run of TPS, the results of which are shown in the bottom panel of Figure 7. The final set of TCEs and the results reported here are based on the second run of TPS. The values of the adopted deemphasis weights are provided in the DV timeseries data products for targets with TCEs.

The top panel of Figure 8 shows the distribution of orbital periods for the final set of TCEs found in Sector 22. The vertical histogram in the right panel of Figure 8 shows the distribution of transit depths derived from limb-darkened transiting planet model fits for TCEs. The model transit depths range down to the order of 100 ppm, but the bulk of the transit depths are considerably larger.

A search for additional TCEs in potential multiple planet systems was conducted in DV through calls to TPS. A total of 813 TCEs were ultimately identified in the SPOC pipeline on 561 unique target stars. Table 3 provides a breakdown of the number of TCEs by target. Note that targets with large numbers of TCEs are likely to include false positives.

Number of TCEs	Number of Targets	Total TCEs
1	369	369
2	147	294
3	33	99
4	10	40
5	1	5
6	1	6
	561	813

Table 3: Sector 22 TCE Numbers

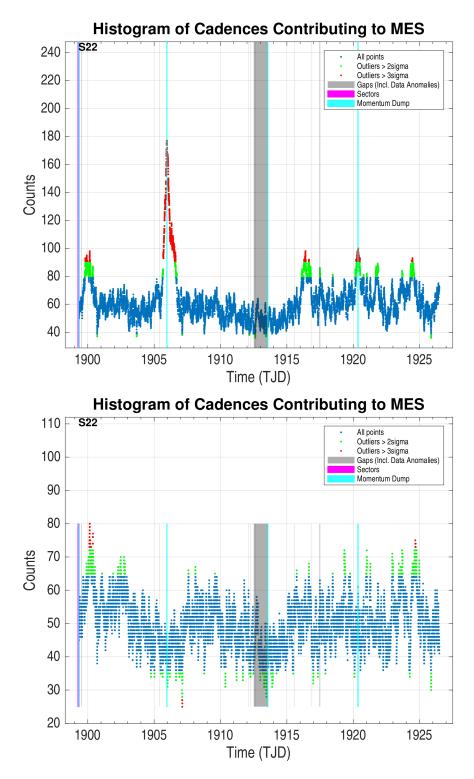

Figure 7: Top panel: Number of TCEs at a given cadence exhibiting a transit signal, based on an initial run of TPS. Any isolated peaks are caused by single events that result in spurious TCEs. These peaks were used to define deemphasis weights that suppress problematic epochs for the transit detection statistics in a second iteration of TPS. Bottom panel: Results from the second run of TPS.

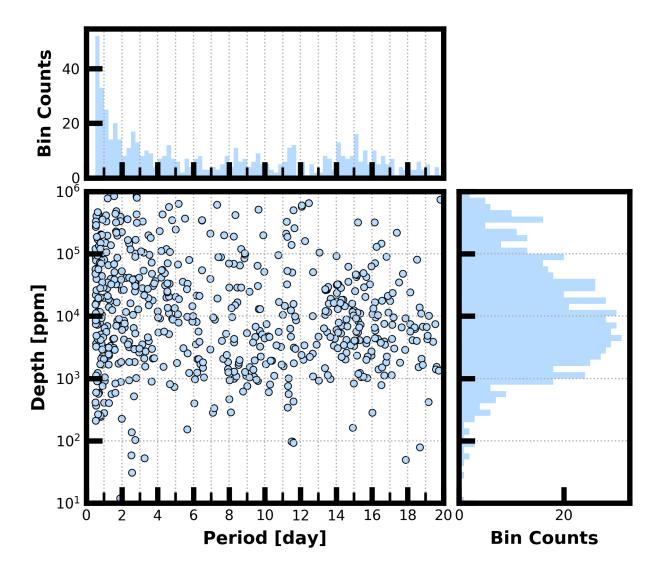

Figure 8: Lower Left Panel: Transit depth as a function of orbital period for the 813 TCEs identified for the Sector 22 search. For enhanced visibility of long period detections, TCEs with orbital period <0.5 days are not shown. Reported depth comes from the DV limb darkened transit fit depth when available, and the DV trapezoid model fit depth when not available. Top Panel: Orbital period distribution of the TCEs shown in the lower left panel. Right Panel: Transit depth distribution for the TCEs shown in the lower left panel.
